

Python fundamentals

A python variable is a bucket or container that store your data

- We declare a variable

```
x = 20
```

age = 20 in this variable we are storing a int-integer (number without a decimal)

```
name = "Rohit"
```

```
Car = "Suzuki"
```

} these are strings - a combination of characters. We have double quotes because it's a string

Print () is a function in python that display what is inside

```
x = 5
```

```
Print (x)
```

```
Surnames = ("Nemukul", "Dagad", "Sitole", "Sisya")
```

```
Print (Surnames)
```

Rules of naming variable.

A variable must start with a letter or an underscore character (-)

name

-name

-name-Surname

name 10

Incorrect variables

2 name = "Rohit"

name surname = "Rohit"

name > Surname

- You can not start a variable name with a number
- You cannot have a space in the name of the variable
- You can not separate the words in a variable name with a dash (-) rather use an underscore (_)
