Logical operators

We can use the logical operators to build conditions
for data filtering as an example

$=$, $!=$, $<$, $>$, $<=$, $>=$

$x = 10$

$y = 20$

```
if x < y:  
    print("Correct")
```

• $x = 50$

$y = 20$

```
if x < y:  
    print("Correct")
```

```
elif x > y:  
    print("Wrong")
```

else:

```
    print("BrightLearn")
```

Python Functions

A block of code that runs when called.

Avoid code repetition

Cuts down the size of a file

makes the code to be more organised.

A function is re-usable.

Built for a specific task.
