

Classification Metrics

- ① Confusion Matrix is a table that is used to describe the performance of a classification model on a set of data where the true values are known

		Actual values		
		Positive (1)	Negative (0)	
(1) Positive		True Positive ①	False Positive	predicted Values
(0) Negative		False Negative ②	True Negative ③	

- ① Predicted : Positive and Actual value : Positive (TP)
- ② Predicted : Negative and Actual value : Negative (TN)
- ③ Predicted : Negative & Actual value : Positive (FN)
- ④ Predicted : Positive and Actual value : Negative (FP)

- ② Accuracy is the number of correct predictions over the total predictions

$$\text{Accuracy} = \frac{\text{Number of correct predictions}}{\text{total number of predictions}}$$
